Class 9: Structural Bioinformatics

Wade Ingersoll (PID: A69038080)

Table of contents

The PDB database

The main repository for biomolecular structure data is the Protien Data Bank (PDB) https://www.rcsb.org/

Let's have a quick look at the composition of this database:

```
# Read in data file
stats <- read.csv("Data Export Summary.csv")

# View it
stats
```

```
           Molecular.Type   X.ray     EM    NMR Integrative Multiple.methods
1          Protein (only) 176,378 20,438 12,709         342               221
2 Protein/Oligosaccharide  10,284  3,396     34           8                11
3              Protein/NA   9,007  5,931    287          24                 7
4     Nucleic acid (only)   3,077    200  1,554           2                15
5                   Other     174     13     33           3                 0
6  Oligosaccharide (only)      11      0      6           0                 1
  Neutron Other   Total
1      83    32 210,203
2       1     0  13,734
3       0     0  15,256
4       3     1   4,852
5       0     0     223
6       0     4      22
```

We need to remove commas:

```
as.numeric(sub(",", "", stats$X.ray))
```

```
[1] 176378  10284   9007   3077    174     11
```

However, this is not efficient so we will use a different function from the **readr** package.

```
library(readr)

stats <- read_csv("Data Export Summary.csv")
```

```
Rows: 6 Columns: 9
-- Column specification --------------------------------------------------------
Delimiter: ","
chr (1): Molecular Type
dbl (4): Integrative, Multiple methods, Neutron, Other
num (4): X-ray, EM, NMR, Total

i Use `spec()` to retrieve the full column specification for this data.
i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

```
stats
```

```
# A tibble: 6 x 9
  `Molecular Type`    `X-ray`    EM   NMR Integrative `Multiple methods` Neutron
  <chr>                 <dbl> <dbl> <dbl>       <dbl>                <dbl>   <dbl>
1 Protein (only)       176378 20438 12709         342                  221      83
2 Protein/Oligosacch~   10284  3396    34           8                   11       1
3 Protein/NA             9007  5931   287          24                    7       0
4 Nucleic acid (only)    3077   200  1554           2                   15       3
5 Other                   174    13    33           3                    0       0
6 Oligosaccharide (o~      11     0     6           0                    1       0
# i 2 more variables: Other <dbl>, Total <dbl>
```

Now we can answer Q1 (Percent X-Ray and EM)

```
n.total <- sum(stats$Total)
n.xray <- sum(stats$`X-ray`)
n.em <- sum(stats$EM)

round( n.xray/n.total * 100, 2 )
```

```
[1] 81.43
```

```
round( n.em/n.total * 100, 2 )
```

```
[1] 12.27
```

> **Q1:** What percentage of structures in the PDB are solved by X-Ray and Electron Microscopy.
>
> **Answer:** X-Ray = 81.43% and EM = 12.27% (see code above for calculations)

Now let's answer Q2

```
n.total <- sum(stats$Total)
protein <- stats$Total[1]

round( protein/n.total * 100, 2 )
```

```
[1] 86.05
```

Q2: What proportion of structures in the PDB are protein?

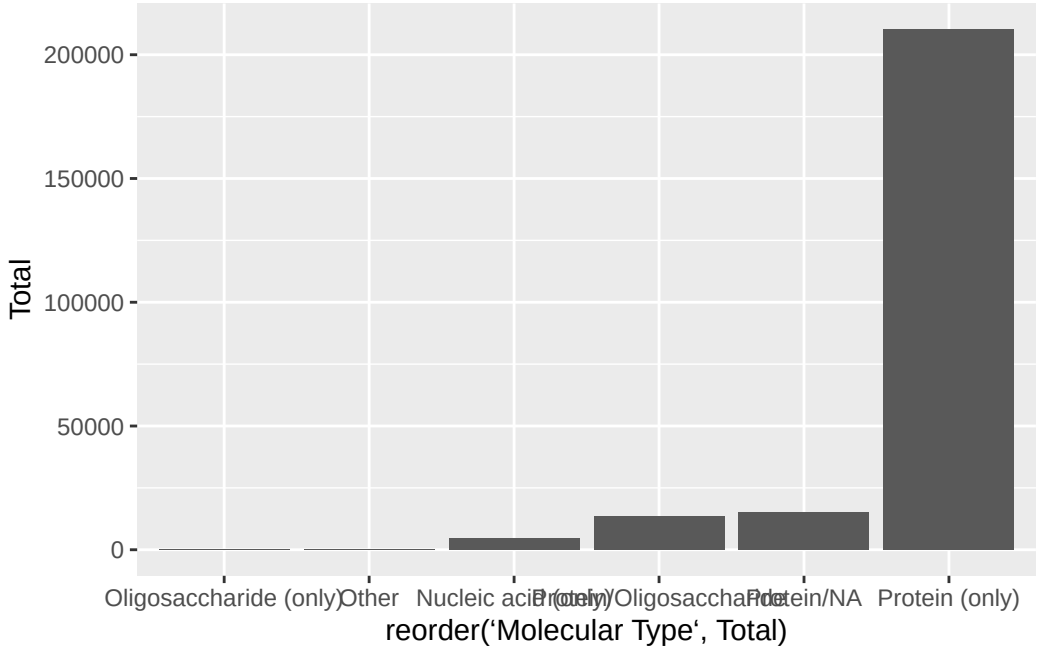
Answer: 86.05% (see code above for calculations)

Now let's answer Q3

> **Q3:** Type HIV in the PDB website search box on the home page and determine how many HIV-1 protease structures are in the current PDB? (Make a barplot overview)
>
> **Answer:** 1,150

```
library(ggplot2)

ggplot(stats) +
  aes(reorder(`Molecular Type`, Total), Total) +
  geom_col()
```



Visualizing structure data

The Mol* viewer embeded in many bioinformatics websites. The homepage is https://molstar.org/ (use pdb accession number 1hsg)

I can insert any figure or image file using markdown format

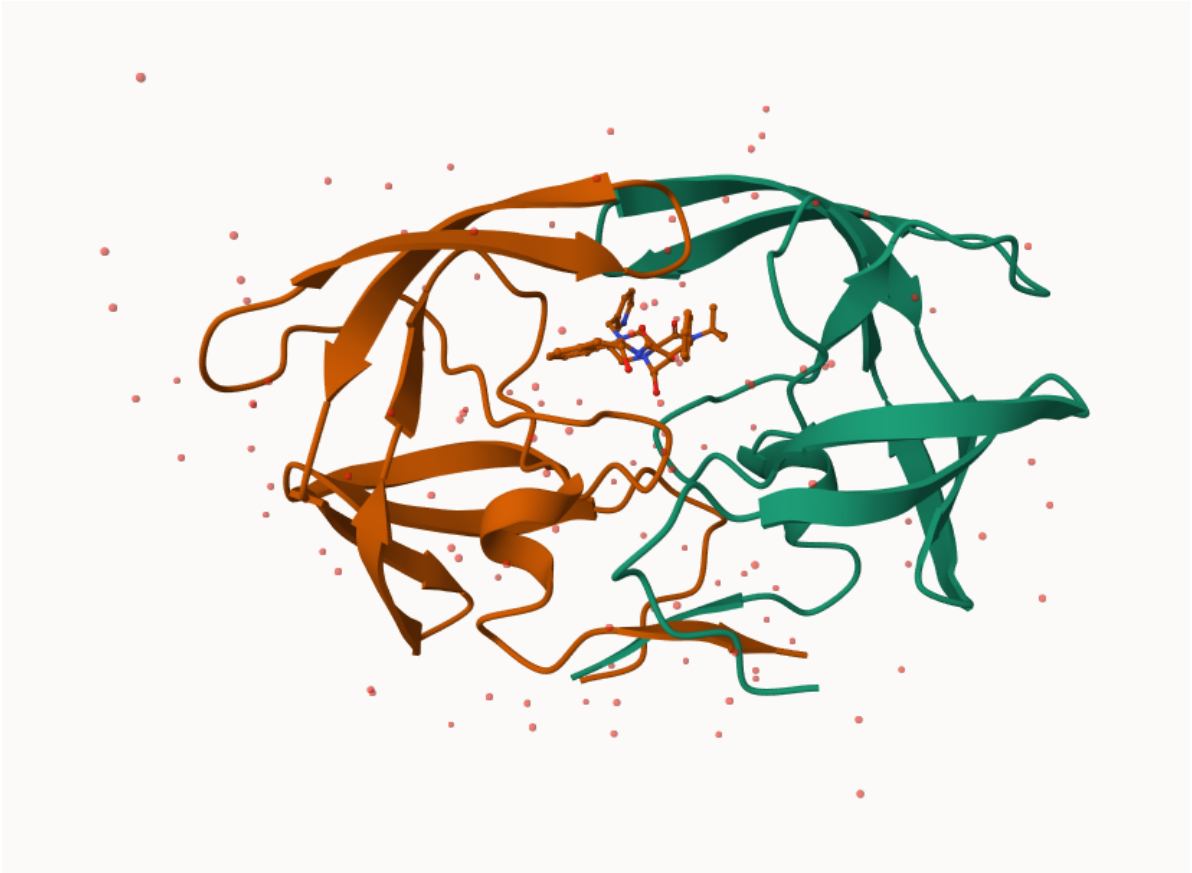


Figure 1: The HIV-Pr dimer with bound inhibitor

Figure 2: The catalytic ASP25 and active-site water

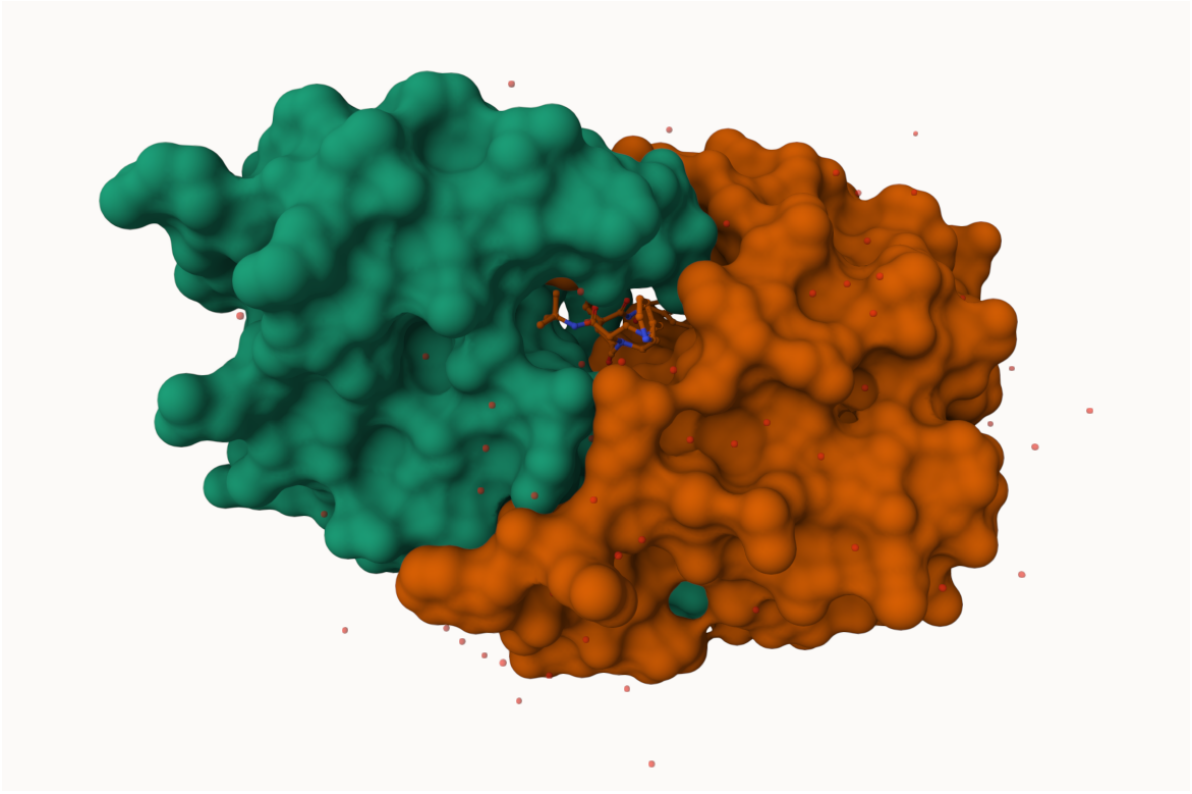

Figure 3: molecular surface

Bio3D package for structural bioinformatics

We can use the bio3d package to read and analyze biomolecular data in R:

```
library(bio3d)

hiv <- read.pdb("1hsg")
```

```
  Note: Accessing on-line PDB file
```

```
hiv
```

```

 Call:  read.pdb(file = "1hsg")

Prediction of functional motions

We can run a Normal Mode Analysis (NMA) to predict large scale motions/flexibility/dynamics of any biomolecule that we can read into R.

```
adk <- read.pdb("1ake")
```

```
  Note: Accessing on-line PDB file
   PDB has ALT records, taking A only, rm.alt=TRUE
```

```
adk_A <- trim.pdb(adk, chain="A")
adk_A
```

```
 Call:  trim.pdb(pdb = adk, chain = "A")

Play with 3D viewing in R

We can use the new **bio3dview** package, which is not yet on CRAN, to render interactive 3D views in R and HTML quarto output reports.

To install from GitHub we can use the **pak** package.

```
# library(bio3dview)
#
# view.pdb(adk)
```

4. Comparative structure analysis of Adenylate Kinase

The goal of this section is to perform **principal component analysis** (PCA) on the complete collection of Adenylate kinase structures in the protein data-bank (PDB).

Adenylate kinase (often called simply Adk) is a ubiquitous enzyme that functions to maintain the equilibrium between cytoplasmic nucleotides essential for many cellular processes. Adk operates by catalyzing the reversible transfer of a phosphoryl group from ATP to AMP. This reaction requires a rate limiting conformational transition (i.e. change in shape). Here we analyze all currently available Adk structures in the PDB to reveal detailed features and mechanistic principles of these essential shape changing transitions.

The **bio3d** package pca() function provides a convenient interface for performing PCA of biomolecular structure data. As we have discussed in previous classes, PCA is a statistical approach used to transform large data-sets down to a few important components that usefully describe the directions where there is most variance. In terms of protein structures PCA can be used to capture major structural variations within a set of structures (a.k.a. structure ensemble). This can make interpreting major conformational states (such as 'active' and 'inactive' or 'ligand bound' and 'un-bound' states) and structural mechanisms for activation or regulation more clear.

Overview

Starting from only one Adk PDB identifier (**PDB ID: 1AKE**) we will search the entire PDB for related structures using BLAST, fetch, align and superpose the identified structures, perform PCA and finally calculate the normal modes of each individual structure in order to probe for potential differences in structural flexibility.

Setup

We will begin by first installing the packages we need for today's session.

Install packages in the R console NOT your Rmd/Quarto file

> **Q10:** Which of the packages above is found only on BioConductor and not CRAN?
>
> **Answer:** msa
>
> **Q11:** Which of the above packages is not found on BioConductor or CRAN?
>
> **Answer:** bio3d-view
>
> **Q12:** True or False? Functions from the devtools package can be used to install packages from GitHub and BitBucket? - True!

Search and retrieve ADK structures

Below we perform a blast search of the PDB database to identify related structures to our query Adenylate kinase (ADK) sequence. In this particular example we use function get.seq() to fetch the query sequence for chain A of the PDB ID 1AKE and use this as input to blast.pdb(). Note that get.seq() would also allow the corresponding UniProt identifier.

```
library(bio3d)
aa <- get.seq("1ake_A")
```

```
Warning in get.seq("1ake_A"): Removing existing file: seqs.fasta

Fetching... Please wait. Done.
```

```
aa
```

```
             1        .         .         .         .         .         60
pdb|1AKE|A   MRIILLGAPGAGKGTQAQFIMEKYGIPQISTGDMLRAAVKSGSELGKQAKDIMDAGKLVT
             1        .         .         .         .         .         60

            61        .         .         .         .         .         120
pdb|1AKE|A   DELVIALVKERIAQEDCRNGFLLDGFPRTIPQADAMKEAGINVDYVLEFDVPDELIVDRI
            61        .         .         .         .         .         120

           121        .         .         .         .         .         180
pdb|1AKE|A   VGRRVHAPSGRVYHVKFNPPKVEGKDDVTGEELTTRKDDQEETVRKRLVEYHQMTAPLIG
           121        .         .         .         .         .         180

           181        .         .         .   214
pdb|1AKE|A   YYSKEAEAGNTKYAKVDGTKPVAEVRADLEKILG
           181        .         .         .   214

Call:
  read.fasta(file = outfile)

Class:
  fasta

Alignment dimensions:
  1 sequence rows; 214 position columns (214 non-gap, 0 gap)

+ attr: id, ali, call
```

Q13: How many amino acids are in this sequence, i.e. how long is this sequence?

Answer: 214

Now we can use this sequence as a query to BLAST search the PDB to find similar sequences and structures.

```
# Blast or hmmer search
b <- blast.pdb(aa)
```

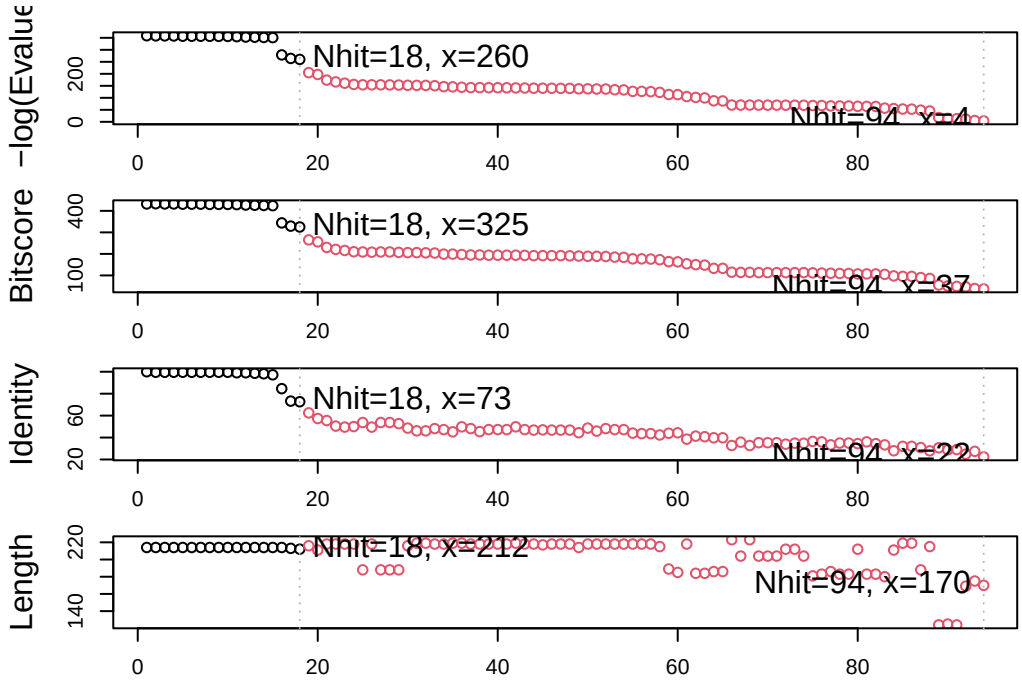
```
 Searching ... please wait (updates every 5 seconds) RID = GG07S70C014
 ..............
 Reporting 94 hits
```

The function plot.blast() facilitates the visualization and filtering of the Blast results. It will attempt to set a seed position to the point of largest drop-off in normalized scores (i.e. the biggest jump in E-values). In this particular case we specify a cutoff (after initial plotting) of to include only the relevant E.coli structures:

```
# Plot a summary of search results
hits <- plot(b)
```

```
  * Possible cutoff values:    260 3
            Yielding Nhits:    18 94

  * Chosen cutoff value of:    260
            Yielding Nhits:    18
```



```
# List out some 'top hits'
head(hits$pdb.id)
```

```
[1] "1AKE_A" "8BQF_A" "4X8M_A" "6S36_A" "8Q2B_A" "8RJ9_A"
```

The Blast search and subsequent filtering identified a total of 13 related PDB structures to our query sequence. The PDB identifiers of this collection are accessible through the `$pdb.id attribute to the hits object (i.e. hits$pdb.id)`. Note that adjusting the cutoff argument (to `plot.blast()`) will result in a decrease or increase of hits.

We can now use function `get.pdb()` and `pdbslit()` to fetch and parse the identified structures.

```
# Download releated PDB files
files <- get.pdb(hits$pdb.id, path="pdbs", split=TRUE, gzip=TRUE)
```

```

Align and superpose structures

Next we will use the `pdbaln()` function to align and also optionally fit (i.e. superpose) the identified PDB structures.

```
# Align releated PDBs
pdbs <- pdbaln(files, fit = TRUE, exefile="msa")
```

```

```

```r
# Vector containing PDB codes for figure axis
ids <- basename.pdb(pdbs$id)

# Draw schematic alignment
#plot(pdbs, labels=ids)

# Plot is too large to render so I took a screenshot and inserted it manually:
```

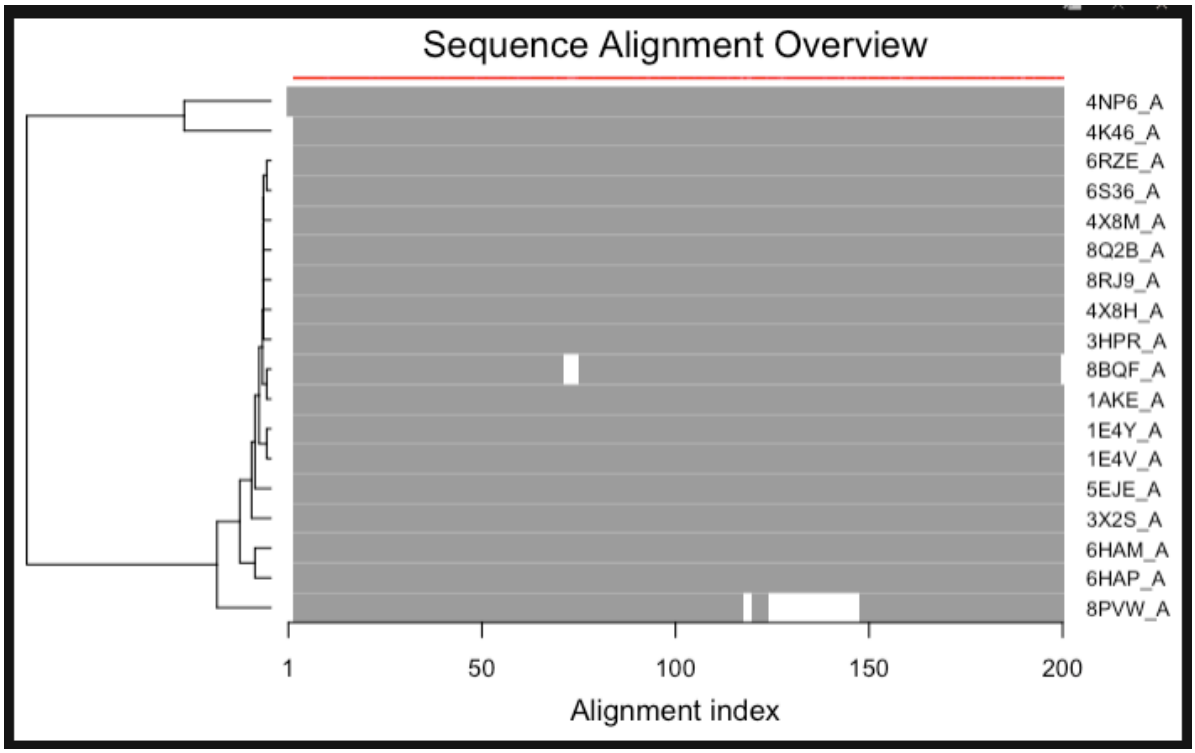

Figure 4: sequence alignment plot

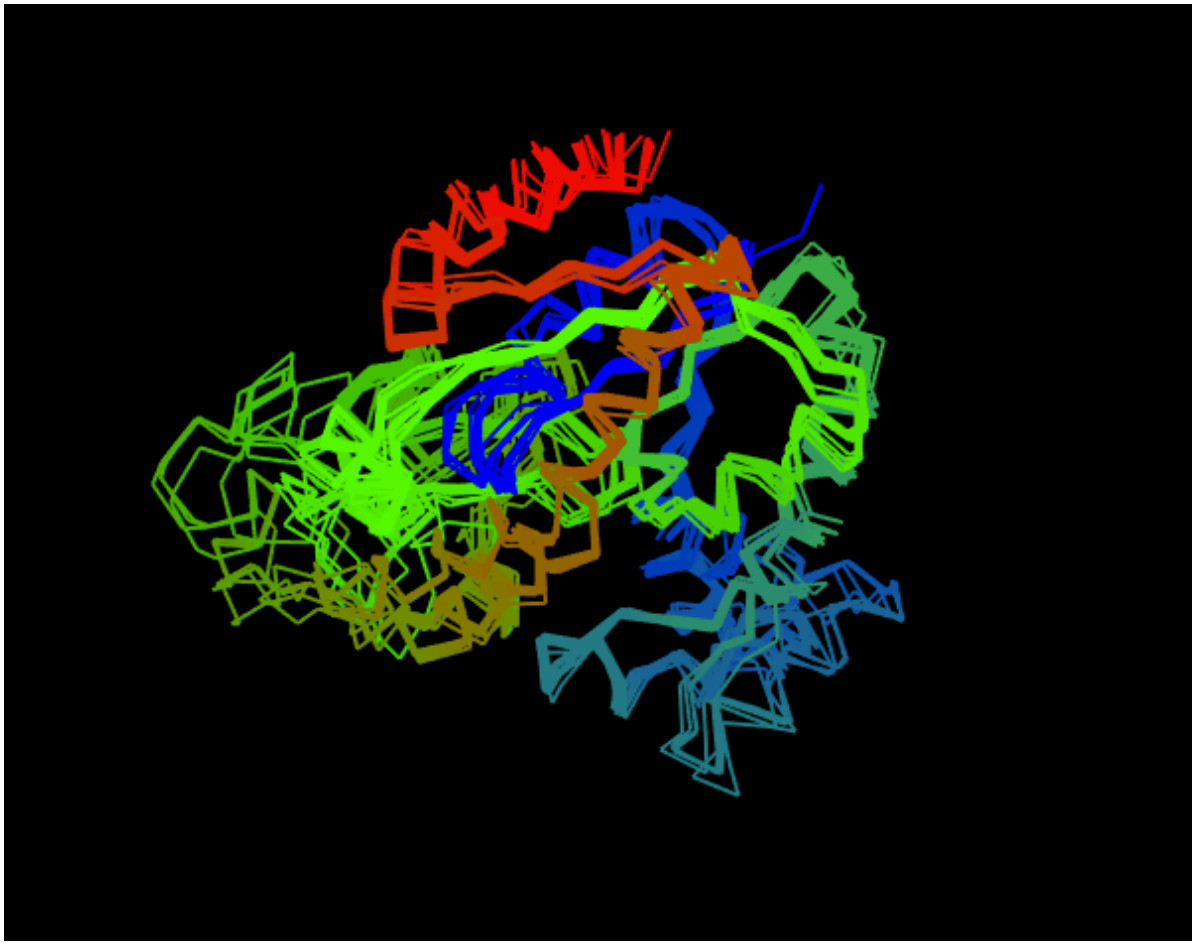
Optional: Viewing our superposed structures

We can view our superposed results with the new bio3d.view view() function:

```
library(bio3d.view)
library(rgl)

view.pdbs(pdbs)
```



Annotate collected PDB structures

The function `pdb.annotate()` provides a convenient way of annotating the PDB files we have collected. Below we use the function to annotate each structure to its source species. This will come in handy when annotating plots later on:

```
anno <- pdb.annotate(ids)
unique(anno$source)
```

```
[1] "Escherichia coli"
[2] "Escherichia coli K-12"
[3] "Escherichia coli O139:H28 str. E24377A"
[4] "Escherichia coli str. K-12 substr. MDS42"
[5] "Photobacterium profundum"
[6] "Vibrio cholerae O1 biovar El Tor str. N16961"
```

We can view all available annotation data:

```

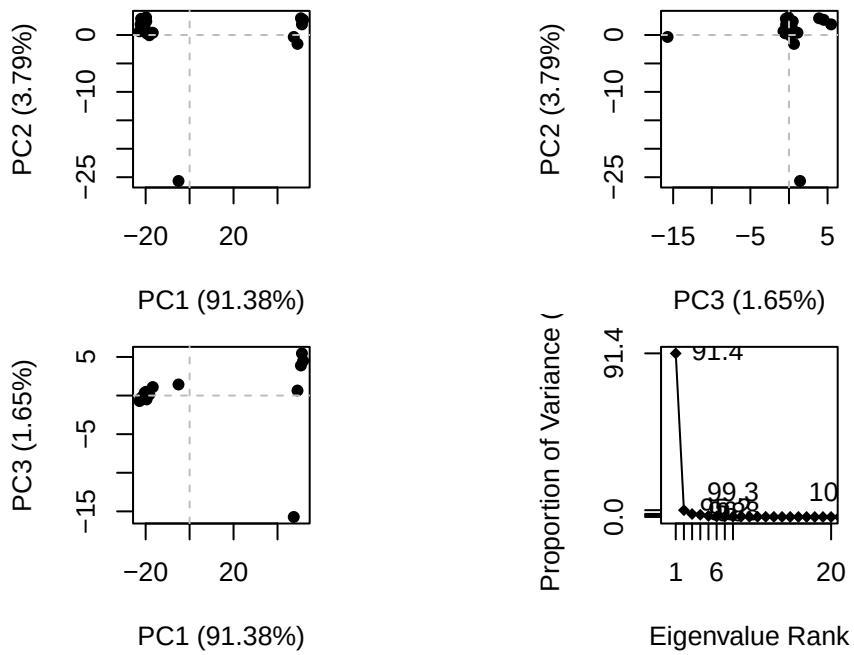
Principal component analysis

Function `pca()` provides principal component analysis (PCA) of the structure data. PCA is a statistical approach used to transform a data set down to a few important components that describe the directions where there is most variance. In terms of protein structures PCA is used to capture major structural variations within an ensemble of structures.

PCA can be performed on the structural ensemble (stored in the pdbs object) with the function `pca.xyz()`, or more simply `pca()`.

```
# Perform PCA
pc.xray <- pca(pdbs)
plot(pc.xray)
```



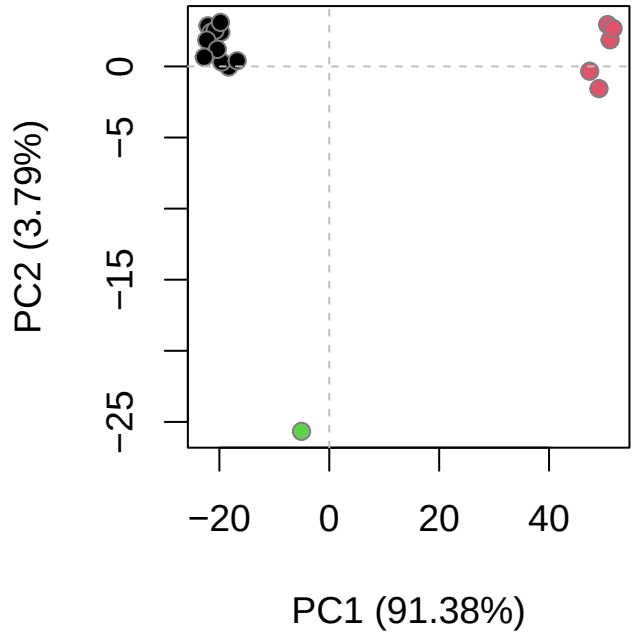
Function `rmsd()` will calculate all pairwise RMSD values of the structural ensemble. This facilitates clustering analysis based on the pairwise structural deviation:

```
# Calculate RMSD
rd <- rmsd(pdbs)
```

```
Warning in rmsd(pdbs): No indices provided, using the 182 non NA positions
```

```
# Structure-based clustering
hc.rd <- hclust(dist(rd))
grps.rd <- cutree(hc.rd, k=3)

plot(pc.xray, 1:2, col="grey50", bg=grps.rd, pch=21, cex=1)
```



The plot shows a conformer plot – a low-dimensional representation of the conformational variability within the ensemble of PDB structures. The plot is obtained by projecting the individual structures onto two selected PCs (e.g. PC-1 and PC-2). These projections display the inter-conformer relationship in terms of the conformational differences described by the selected PCs.

5. Optional further visualization

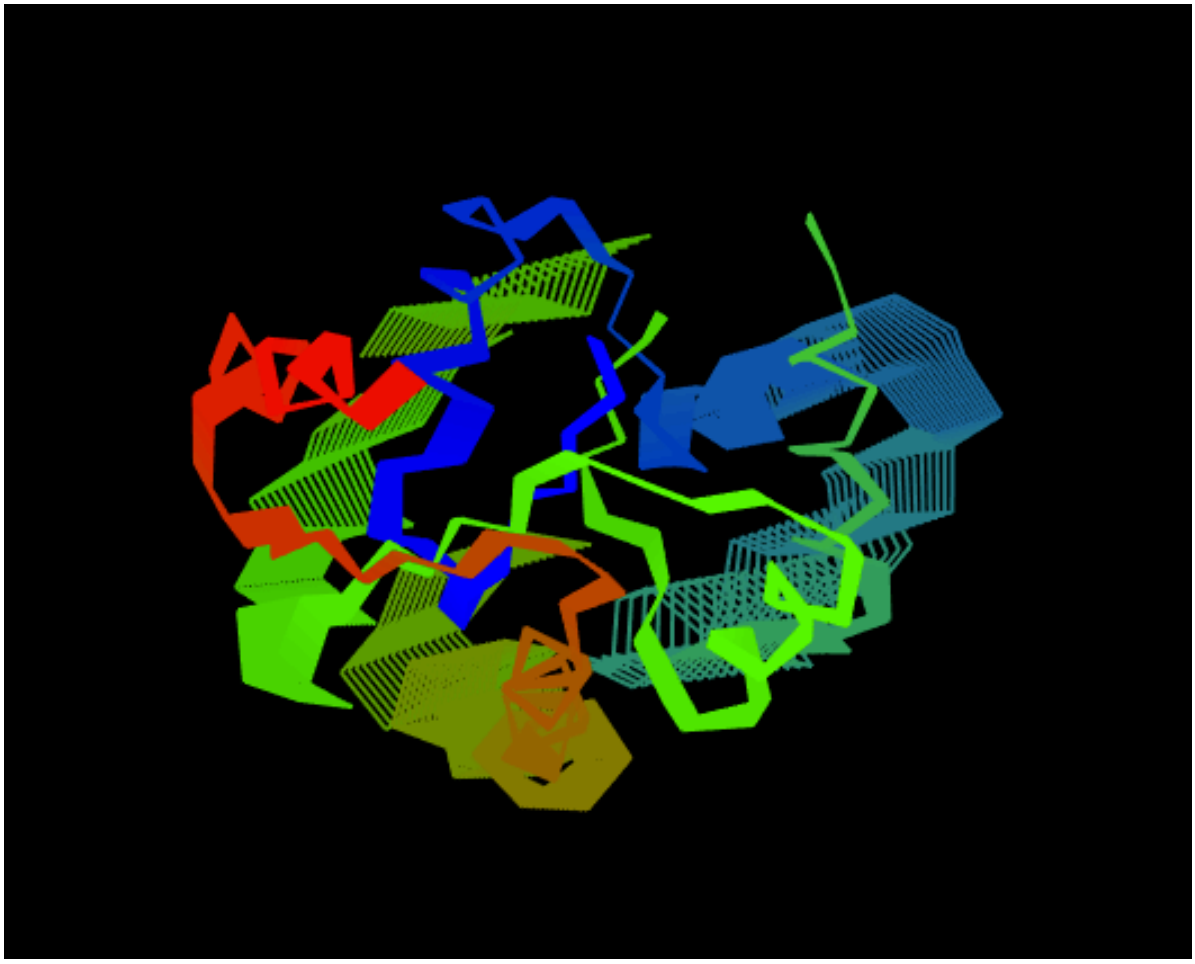
To visualize the major structural variations in the ensemble the function `mktrj()` can be used to generate a trajectory PDB file by interpolating along a give PC (eigenvector):

```
# Visualize first principal component
pc1 <- mktrj(pc.xray, pc=1, file="pc_1.pdb")
```

We can also view our results with the new bio3d.view view() function:

```
view.xyz(pc1)
```

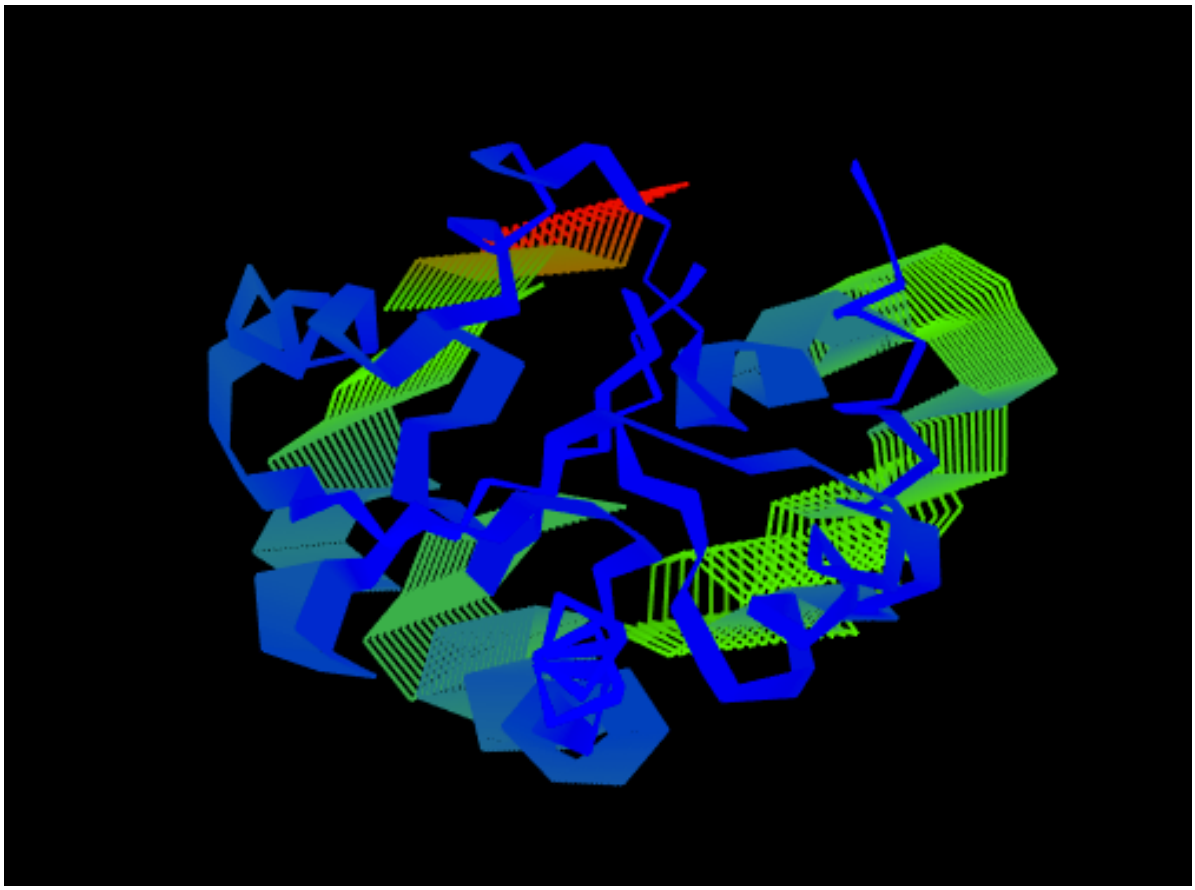
```
Potential all C-alpha atom structure(s) detected: Using calpha.connectivity()
```



We could set the color to highlight the most variable regions like so:

```
view.xyz(pc1, col=vec2color( rmsf(pc1) ))
```

```
Potential all C-alpha atom structure(s) detected: Using calpha.connectivity()
```



We can also plot our main PCA results with ggplot:

```
#Plotting results with ggplot2
library(ggplot2)
library(ggrepel)

df <- data.frame(PC1=pc.xray$z[,1],
                 PC2=pc.xray$z[,2],
                 col=as.factor(grps.rd),
                 ids=ids)

p <- ggplot(df) +
  aes(PC1, PC2, col=col, label=ids) +
  geom_point(size=2) +
  geom_text_repel(max.overlaps = 20) +
  theme(legend.position = "none")
p
```
